The Role of Information for Retirement Behavior: Evidence based on the Stepwise Introduction of the Social Security Statement

Giovanni Mastrobuoni
Collegio Carlo Alberto, CeRP, Netspar*

August 2010

Abstract

In 1995, the Social Security Administration started sending out the annual Social Security Statement. It contains information about the worker's estimated benefits at the ages 62, 65, and 70. I use this unique natural experiment to analyze the retirement and claiming decision making. First, I find that, despite the previous availability of information, the Statement has a significant impact on workers' knowledge about their benefits. These findings are consistent with a model where workers need to gather costly information in order to improve their retirement decision. Second, I use this exogenous variation in knowledge to analyze the optimality of workers' decisions. Several findings suggest that workers do not change their retirement behavior: i) Workers do not change their expected age of retirement after receiving the Statement; ii) monthly claiming patterns do not show any change after the introduction of the Social Security Statement; iii) workers do not become more sensitive to Social Security incentives after receiving the Statement. More research is needed to establish whether workers are already behaving optimally or they are not, but the information contained in the Statement is not sufficient to improve their retirement behavior.

Keywords: social Security statements, retirement expectations, retirement behavior, social security incentives

JEL classification codes: H55, J26

*This research was supported by the Sandell Grant of Boston College, from the U.S. Social Security Administration (SSA) as part of the Retirement Research Consortium (RRC). Wioletta Dziuda has been of invaluable help. I would also like to thank Orley Ashenfelter, Raj Chetty, Bo Honoré, Alan Krueger, and Harvey Rosen and all participants and all seminar participants in Princeton, Social Security Administration, Syracuse University, Universitat Pompeu Fabra, University College London, University of California Merced, and Warwick University, in particular, in particular Jane Fortson, Radha Iyengar, Joyce Manchester, Nisreen Salti, Martin Schonger, Perry Singleton, David Weaver, Matt Weinberg, and Luke Willard. A special thanks goes to Jae Song, who provided the data, an initial benefit calculator, and also organized my first summer stay at the Social Security Administration.

1 Introduction

Many older workers know little about their retirement benefits.¹ In order to help workers make provisions for their retirement, the Social Security Administration (SSA) introduced the Social Security Statement in 1995. The Statement is a concise record of past earnings and a summary of estimated benefits as a function of different retirement ages. It is mailed to all workers paying payroll taxes, typically three months before their birthday. In 2008 the cost of sending an individual Statement was only about 36 cents, but given the large number of Statements sent each year, the total cost is 53 million dollars (?). This paper evaluates whether sending the Statement increased workers' knowledge and influenced retirement behavior. The more general question is how workers make decisions, and to what extent these decisions change when workers are provided with additional information.

In 1995 the SSA was required to mail the annual Statement—then named the Personal Earnings and Benefit Estimate Statement—to all workers age 60 and older and in later years it has been sent out in phases. The stepwise introduction allows me to identify the effect of the Statement controlling for age and time. Using The Health and Retirement Survey (HRS) data, I find that workers aged 55 to 64 who received the Statement and had not previously contacted SSA regarding their benefits are 20 percentage points (50 percent) more likely to be able to provide an estimate of their future benefits than workers that did not receive the Statement.

While these are very large effects, if workers were behaving optimally this additional information would not substantially change workers' retirement or saving behavior. In contrast, some workers might just be procrastinating: the cost of becoming informed and learning the optimal retirement age and savings are borne upfront, while the corresponding utility gains are received only sometime later. Workers with high discount rates should, therefore, seek information later. For these workers, the Social Security Statement might actually induce changes in behavior. I use three different ways to measure changes in behavior. First, I look at whether workers are more likely to update their retirement plans upon receiving a Statement. Then, I check whether workers change their actual claiming behavior. Finally, I see whether workers

¹See among others, ?, ?, ?, ?, ?.

are more likely to respond to the retirement incentives provided by the Social Security benefit formula after receiving a Statement.²

I find no evidence that receiving the first Statement induces workers to update their expectations. Social Security claiming patterns also show no change upon the introduction of the Statement. Retirement decisions do not become more sensitive to Social Security incentives. Overall, the results suggest that either workers were already behaving optimally or that the additional information provided by the Statement isn't sufficient to improve uniformed workers' retirement choices.

2 Literature review

2.1 Retirement Behavior

Standard economic theory assumes that all agents base their retirement decisions on forward-looking variables. ? provide a comprehensive survey of studies that modeled retirement behavior. These studies typically assume implicitly that workers know their future benefits as a function of their retirement age and are able to compare future streams of benefits. Empirical evidence, however, suggests that these are strong assumptions. When asked, only around 50 percent provide an estimate of their expected Social Security benefits.³ ? show that fewer than 30 percent of respondents are able to estimate their future benefits to within about \$1,500 per year. Moreover, ? show that financial illiteracy is widespread among older Americans. Only half of the age 50+ respondents can correctly answer two simple questions regarding interest compounding and inflation. Is it then reasonable to assume those same respondents are able to compute their retirement incentives, which typically involve relatively complex calculations?

Despite the apparently little knowledge about retirement incentives, the fact that people seem to respond to incentives when making their retirement decisions has been called by ? an "important empirical puzzle in the retirement literature." ? try to test the robustness of retirement models when a measure of knowledge about benefits is added to the retirement regression.

²The administrative records are used to compute retirement incentives (see, for example, ???).

³See ??. In my sample that focuses on workers aged 55 and above, two-thirds of workers are able to provide an estimate.

They find that explicitly controlling for knowledge does not affect workers' responsiveness to changes in the present value of the stream of Social Security benefits from postponing retirement, which are also called accruals. ? go one step further and analyze how the interaction of knowledge and accruals affects workers' decisions. The authors find that responsiveness to pension incentives is entirely driven by the 20 percent of workers who perceive them correctly.⁴ The validity of using measures of knowledge in the regressions, however, is questionable as knowledge is endogenous: workers gather information when they approach their expected retirement age. Most workers contact the SSA in order to learn about their future Social Security benefits. Once they do so, the data show that they become more likely to provide a benefit estimate, and their estimate becomes more precise.⁵ This is not surprising. The SSA's benefit formula is complicated, and workers would have a hard time trying to calculate their expected benefits without the SSA's help. But this additional information is only valuable if individual workers can use it and are unconstrained with respect to their retirement choice, i.e. workers who face health problems or have liquidity constraints tend to retire as soon as possible. Consistent with this, I find that wealthier and healthier workers are significantly more likely to get informed.

2.2 The Social Security Statement

Economists have not studied the introduction of Statements, apart from the Government Accountability Office's (GAO) evaluation of their understandability.⁶ Therefore, ? concluded that: "Given the importance of Social Security benefits to so many Americans, it is surprising how little academic attention has been given to the content and implications of Social Security benefits" and "what is clear is that the Social Security Statement is one of the most important communication that the federal government sends out to the general public each year, and as such the document deserves much more attention from public official and academic writers than

⁴They do not find any link between knowledge and Social Security accruals, which they consider a result of data limitations. A limitation of their test, and as a matter of fact, of mine as well, is that they can measure if workers correctly perceive their Social Security benefits, but not if they correctly compute their forward-looking Social Security incentives, like the present-discounted stream of benefits.

⁵? show that having contacted the SSA is the strongest predictor for being knowledgeable about Social Security benefits.

⁶See GAO/T-HEHS-96-210, GAO/HEHS-97-19, GAO/HEHS-98-228, GAO/T-HEHS-00-101, GAO-05-192 on www.gao.gov.

it has received to date.” According to the GAO reports the overall public reaction to receiving an unsolicited Statement has been favorable. The reports cite a nationally representative survey in which, as predicted by ?, “the majority of the respondents indicated they were glad to receive their Statements and 95 percent of them said the information provided was helpful to their families.” The April 2005 report finds that 66 percent of workers remember receiving a Statement (unfortunately they do not provide this number by age groups), and that 90 percent of those who remember receiving a Statement say that they remember the amount of estimated Social Security benefits. The results of a Gallup survey revealed that individuals who had received a Statement had a significantly increased basic understanding of Social Security, and understanding of some important basic features of Social Security: the amount of Social Security benefits depends on how much people earned; Social Security pays benefits to workers who become disabled; Social Security provides benefits to dependents of workers who die (see <http://www.ssa.gov/>.) According to the 2004 Retirement Confidence Survey, 80 percent of workers use retirement benefit Statements (not necessarily only Social Security Statements) and 20 percent find them the most helpful tool in retirement and claiming decision making (?). Jackson analyzes the content of the Social Security Statement, and reports how because of various cognitive biases workers may misinterpret the value of their benefits. He then suggests that including the present discounted value of Social Security benefits may facilitate the comparison with other sources of income and minimize labor market distortions.

3 Exogenous Variation in Knowledge

3.1 The Phasing In Schedule of the Statement

The administration started sending the Statements in 1995. The main purpose is to inform the public about benefits under SSA programs, to aid in financial planning, and to ensure the worker’s earnings records are complete and accurate. The Statement contains expected Social Security benefits at the early (62), the normal (usually 65, though increasing since 2003), and the late (70) retirement age as well as the worker’s entire earnings history. The Statement

also informs workers about spouse’s benefits, survivors’ benefits, and disability benefits.⁷ The Statement does not report the present discounted value of these benefits, also called the Social Security Wealth (SSW).

The SSA was required to mail the annual Statement—then named the Personal Earnings and Benefit Estimate Statement—to all workers age 60 and older. In later years it has been sent according to the following (year, age) combinations: (1996, 58+), (1997, 53+), (1998, 47+), (1999, 44+), (2000, 25+). Workers usually receive their Statement one month before their birthdays.⁸ This seems to be a good timing since 65 percent of all workers claim immediately after their birthdays (15 percent of the claims occur in January and the remaining workers tend to claim uniformly across the year). Later I show that apart from age and year no other observable characteristics of workers are able to predict the receipt of a Statement. Conditional on age and year effects it is as if it was randomly assigned. With precise information on the date of the HRS surveys and on the date of birth of the respondents and with internal documents of the SSA, I reconstruct the exact same schedule used by the Social Security Administration to send out the letters. The introductory schedule was based on fiscal years, which start in October, and workers born in the same year may or may not have received a Statement when the Statements were first send out, depending on whether they were born before or after October. I will later exploit this variation within birth cohorts together with variation in the interview date across survey respondents to set up a quasi-experiment of retirement behavior. The treatment is going to be receiving a Social Security Statement.

3.2 The Statement’s “Treatment”

Assuming that getting informed is costly, a worker will acquire new information about his retirement benefits when, based on his prior over the whole distribution of his retirement benefits (which are function of the retirement age he/she believes that the expected gains of information outweigh the cost of information. Intuitively, information matters when better

⁷In the Appendix provide a sample of the Social Security Statement. Earlier versions of the Statement can be found in reports by the GAO, although they changed little over time.

⁸In 2000 the SSA started sending the Statement three months before the worker’s birthday.

knowledge about the benefits can influence retirement or consumption, in other words, when variation in benefit patterns generate variations in utility. If, for example, the prior is such that the worker strongly believes that it is optimal to retire as soon as possible, it might not be optimal for him to collect additional information. Factors that can generate such a boundary solution are high discount rates, high disutility from work (like health issues), high mortality, and low risk aversion. Moreover, workers need to be able to evaluate their retirement incentives, which are complicated functions of their benefits and of their family status. Financially illiterate workers, unable to compute those incentives, might also choose not to get informed.

The main effect of the Statement is to considerably reduce the cost of information, which should help workers to make better retirement choices. But if workers select into the unknowledgeable state, changes in retirement behavior are expected to be lower than in a situation where knowledge was randomly assigned. I focus on retirement and claiming behavior as later in life workers can hardly influence their entitlements in any other way.

It is important to note that workers have always had the option to ask the SSA to compute their expected benefits (it would usually take 4 to 6 weeks to receive an estimate). Before the Statements started circulating according to the HRS around 50 percent of the respondents would contact the SSA by age 62. Workers could either call a 1800 number, or visit one of the many local SSA offices (across States there is one office every 200-300 thousand inhabitants). According to the HRS, contacting the administration had an enormous effect on the (unconditional) probability of providing a Social Security benefit estimate, almost doubling the probability of providing a benefit estimate from 46 to 88 percent. Before analyzing the effect of the Statement it is therefore important to analyze the selection issue (calling the SSA for a benefit estimate). Appendix A contains a description of the data and for the corresponding summary statistics.

Column (1) in Table 1 shows that, apart from age (multiplied by 1/2 for a reason that will be clear shortly), the three strongest predictors for contacting the SSA are the level of education, race, and wealth. Having less than a high school degree and being black, reduce the probability of contacting the SSA by 11 and 8 percentage points. Consistent with the theory,

wealthier workers, therefore workers that are less likely to be liquidity constrained, are more likely to contact the SSA. The effects are very large. Compared to workers that are in the first wealth quartile, workers with wealth above the median are 18 to 22 percentage points more likely to contact the SSA. Healthy workers are, compared to workers in fair and poor health, more likely to contact the SSA.

In column (2) I additionally control for variables that are not available for the whole sample. While more experienced workers are significantly more likely to contact the SSA, the coefficient on the subjective life-expectancy is not significant.⁹ Since the SSA's actuarial adjustments for postponing retirement are based on the average life-expectancy workers with a low subjective life-expectancy should be less likely to get informed if they know that they should follow the simple rule of retiring and claiming the benefits as soon as possible. On the other hand, workers with a high life-expectancy should do the opposite, claim as late as possible (70). Checking for non-linearities does reveal that workers in the first and the last quartile of the distribution of subjective life-expectancy are less likely to get informed, but the effects are not significant.¹⁰

Around 35 percent of workers age 65 receive a private pension. The incentives of getting informed might differ by whether workers receive a pension or participate in a defined benefit or defined contribution plan, both because pensions change the liquidity constraint and because pensions change the overall retirement incentives. Receiving a pension and participating in a pension plan do not significantly change the probability of contacting the SSA, even when I focus on those who do not yet receive a pension income.¹¹

The respondents financial planning time horizon, information available from the HRS's first wave, is another good predictor of contacting the SSA. How far in advance workers are planning is certainly related to their time preference and consistent with this I find that the longer the planning time horizon the more likely it is workers contact the SSA. It is important to notice that even after controlling for health, wealth, mortality, and proxies of time preference workers

⁹The subjective life-expectancy is measured as the self-reported probability of surviving age 75 divided by the implied probability from the Vital Statistics life tables that someone of the respondent's age and gender will live to be 75.

¹⁰Results available upon request.

¹¹Results available upon request.

without a high school degree are 10 percentage points less likely to contact the SSA. In the last column I additionally control for occupation fixed effects, which does not change these results.

Summing up, workers who didn't contact the SSA before the introduction of the Statement tend to be younger, with lower levels of education, in poor health, poor, with less labor market experience, and less likely to plan many years in advance. Next I show that these workers are more likely to improve their knowledge about their benefits upon receiving a Statement, which is consistent with the idea that information is costly.

3.3 The Effect of the Statement on Workers' Knowledge about Retirement Benefits

In all HRS waves workers are asked about their expected retirement age and their expected Social Security benefits. In the absence of any informational cost we would expect the Statement to have a negligible effect on workers' knowledge.

Column (1) in Table 2 shows the effect of the Statement on the probability of reporting Social Security benefits,¹² estimated using a linear probability model. Thirty-four percent of workers aged between 55 and 65 do not report a benefit estimate. I control for age fixed effects, year, gender, level of education, marital status, race, and labor market experience (number of years with positive earnings). The introduction of the Statement reduces the probability of not reporting an estimate by 6.25 percentage points. Controlling also for year, wealth and health fixed effects (column 2) the reduction is equal to 4.48. This 15 percent drop in the probability of being unreported can be interpreted as an average treatment effect. Being black and not having a high school degree are both very strong predictors for not knowing the future amount of the benefits. But some workers that didn't contact the SSA before receiving the Statement might have contacted the administration later on, showing an improvement that I am now attributing to the Statement.

In order to evaluate this bias let me define the event "contacting SSA" as $C \in \{0, 1\}$ and "not being able to provide an estimate" as $N \in \{0, 1\}$. I need to estimate the improvement in

¹²The dependent variable is equal to one when workers respond that they "don't know" their Social Security benefits. The very few workers who refuse to respond are not included in the regressions.

$\Pr(N = 1)$ that would have happened independently of the Statement $T \in \{0, 1\}$ over the time distance t between HRS surveys (2 years):

$$\Pr(N_t = 1|C_{t-2} = 0, T = 0) - \Pr(N_{t-2} = 1|C_{t-2} = 0, T = 0). \quad (1)$$

Conditioning on $T = 0$, by the law of total probability:

$$\begin{aligned} \Pr(N_t = 1|C_{t-2} = 0) &= \Pr(N_t = 1|C_t = 0) \Pr(C_t = 0|C_{t-2} = 0) \\ &+ \Pr(N_t = 1|C_t = 1) \Pr(C_t = 1|C_{t-2} = 0). \end{aligned} \quad (2)$$

One way to estimate the probability that a worker contacts the administration within a 2-year period $\Pr(C_t = 1|C_{t-2} = 0)$ is to use the cross-sectional information using age as a measure of time. Our estimate of $\Pr(C_t = 1|C_{t-2} = 0)$ is going to be equal to the coefficient on age from Table 1. Age is multiplied by 1/2 in order to estimate the probability over a 2-year period.

Although I don't know $\Pr(N_t = 1|C_t = 1) = E(N_t|C_t = 1)$ and $\Pr(N_t = 1|C_t = 0) = E(N_t|C_t = 0)$ for the years after 1994, I can estimate these probabilities using data from the 1992 and 1994 waves assuming that the probability of contacting SSA and the effects from contacting SSA wouldn't have changed over time. Given these assumptions the overstatement of the effect of the Statement for workers who didn't contact SSA is approximately equal to 3 percentage points (approximately 30 percent) when using data up to 1996:

$$[E(N_{t-2}|C_{t-2} = 1) - E(N_{t-2}|C_{t-2} = 0)]P(C_t = 1|C_{t-2} = 0) = 0.27 \times 0.08 = 0.02. \quad (3)$$

The overall effect would thus be biased by this amount times the fraction of workers who did not contact the administration ($0.02 \times 0.66 = 0.014$, again a 30 percent bias).

I estimate a regression model with known probabilities of misclassification of the variable C in order to use the whole data set, and reach a similar conclusion. Defining C^* as the true event and C as the misclassified one, the true effect of the Statement for group x is proportional to

the misclassified one

$$\begin{aligned}
& [E(N|C = 0, T = x) - E(N|C = 1, T = x)] \\
& = [E(N|C^* = 0, T = x) - E(N|C^* = 1, T = x)] \\
& \quad \times \Pr(C^* = 0|C = 0), \quad x = 0, 1
\end{aligned} \tag{4}$$

where the factor of proportionality is the probability of correctly classifying $1 - C$. Controlling for other X 's, it can be shown that the estimated true effect of the Statement is equal to $\hat{\beta}_{11}$ in the following linear model:¹³

$$\begin{aligned}
N = & \beta_{00} + \beta_{01} (1 - C) \Pr(C^* = 0|C = 0, X) + \beta_{10} T_1 \\
& + \beta_{11} (1 - C) \Pr(C^* = 0|C = 0, X) T_1 + X' \gamma + \epsilon.
\end{aligned} \tag{5}$$

This is the specification used from column (3) of Table 2 on, where I interact the probability of not having contacted the SSA and the post-Statement variable. This way I measure the treatment effect on the treated, and indeed the entire effect of the Statement is concentrated among those who never contacted the SSA (66 percent of the sample). Columns (3) and (4) show that not having contacted the SSA increases the initial probability of not reporting an estimate in the pre-Statement period by 26 percentage points, a large effect.

For those that don't contact the SSA, the Statement reduces the probability of not reporting an estimate by 10 percentage points, approximately one third of the initial difference. Column (4) shows that controlling for year, health and wealth does not change the estimated effects of the Statement.¹⁴

The last two columns of Table 2 report a placebo regression where I simulate the introduction

¹³In order to control for the variation that is due to the first step, I can either use a modified version of ?'s two-step estimator that accounts for the panel structure (dependence over time), or I can simply bootstrap clusters of individuals and then run the first and second step. Since doing so has negligible effects on the standard errors (mainly due to the precision of the estimate of $\Pr(C_t = 1|C_{t-2} = 0, X)$), the analysis is carried out conditional on the estimate from the first stage.

¹⁴The results are not different when, disregarding an endogeneity problem, I also control for the time left from the expected retirement date (results available upon request).

of the Statement with a lag of exactly four years. The sample is based on HRS respondents that already received a Statement. Not controlling for year, wealth and health fixed effects the placebo coefficient is negative, while controlling for those fixed effects the coefficient becomes positive. In both regressions the coefficient is not significantly different from zero, suggesting that simple trends are not driving the “treatment” results.

The effect on knowledge could be different at different ages, and thus could have very different effects on retirement behavior. The effect of the Statement might be concentrated at younger ages with small potential of changing retirement behavior. In order to capture how the Statement can differently affect different age groups, the first column in Table 3 reports for each age the fraction of workers who have contacted the SSA. Since almost all workers claim by age 65, the table is truncated at age 64. Most workers contact the SSA when they are close to retirement. Around 30 percent call in their 50s, while an additional 20 percent call when they approach the early retirement age.

In the remaining columns of Table 3, I analyze how at different ages the probability of reporting a benefit estimate changes upon receiving a Statement.¹⁵ The sample is split into those who did and those who didn’t contact the SSA (using again a model with misclassification errors and known probabilities of misclassification). Among those who contacted the SSA there is a clear reduction in the probability of not reporting an estimate as they approach the early retirement age. There is no such pattern for those who didn’t contact the SSA in the pre-Statement period. In the post-Statement period, there is a clear improvement around the early retirement age. The effect of the introduction of the Statement can be seen by looking at the *Pre – Post* columns. Among those who contacted the SSA most differences are not significantly different from zero. On the other hand, among workers who didn’t contact the SSA, the Statement reduced the fraction of workers that are unable to provide an estimate by around 10 percentage points up to age 58 and 20 percentage points afterwards. In relative terms, the effect around the early retirement age is to reduce the fraction of workers that are

¹⁵I performed a similar analysis using instead of age the expected number of remaining years from retirement, and the results were very similar.

unable to provide a benefit estimate by almost one half.¹⁶ After age 58 the differences are significant at the 1 percent level (except at age 64 where the sample size is also very small).

Next, I analyze whether the Statement improves the estimates of those who provide an estimate. Figure 1 shows the density of the forecast error (the difference between the expected and the actual benefits) for those workers who did and didn't contact the SSA.¹⁷ ¹⁸ The upper figures are unconditional errors, while the lower ones are residual errors after conditioning on year, age, age squared, gender, marital status, race, and educational attainment. Errors seem to be approximately distributed symmetrically around zero, which suggests that, on average, there is no prediction bias. In the pre-Statement period (solid line) the variability of the errors for workers who didn't contact the SSA is much larger than for those who contacted the SSA; this difference seems to disappear once the Statement is introduced (dashed line). As before, this change in the distribution of the error term is likely to be slightly upward biased by the fact that some workers would have contacted the SSA in the absence of the Statement.

I can judge the expected improvement that is not attributable to the Statement (dotted line) by plotting the corresponding pre-Statement density, substituting, with probability equal to the probability of contacting the SSA over a two-year period, workers who didn't contact the SSA with workers who contacted the SSA.¹⁹

In Table 4, I test whether the distributional differences in Figure 1 are significant. For workers who didn't contact the SSA I use the pre-Statement density that controls for the expected improvements (dashed line). Most of the improvement seems to lie within one standard deviation from the mean, which is why I test if the ratio of the pre-Statement to the post-

¹⁶The effect at even earlier ages are small. Workers in their 40s and early 50s are only 3-6 percentage points more likely to provide an estimate as a consequence of receiving the Statement (results available upon request). This casts some doubt on the utility of sending the Statements to young workers that seem to show little interest for them.

¹⁷Benefits are expressed in 2003 dollars using the CPI. The expected benefits refer to what the worker would get at his expected retirement age. The actual benefits are computed using what workers actually ended up receiving in later waves. Using actual benefits computed using the administrative records gives similar results. I take into account that actual Social Security benefits refer to the year before the interview. Results using the relative forecast error are similar.

¹⁸Note that to highlight the distributional differences I truncated the distribution of the error at $\pm\$1000$ (3 percent of the sample).

¹⁹These graphs use only information up to 1996 and therefore the probability is simply equal to 8 percent.

Statement variance is larger than one, truncating the error at $\pm\$1000$, $\pm\$500$, and $\pm\$300$.²⁰ The p-value of this one-sided test for those who didn't contact the SSA is zero for the \$1000 truncation and close to zero as I concentrate the analysis to errors that are closer to the median. For those who contacted the SSA I can reject the hypothesis that the variance decreased after the introduction of the Statement. It is worth noting that although the variance of the forecast error decreased for those who were previously uninformed, similarly to what I observed before for the probability of reporting an estimate, their post Statement errors are still larger compared to the other group.

The above analysis suggests that thanks to the Statement some workers became more knowledgeable about their Social Security benefits. Workers who received a Statement because they contacted the administration before 1995 do not show improvements or reductions in knowledge, which suggests that the automated Statements do not contain more or less information compared to the ones the administration would mail once contacted.

Workers who didn't contact the administration, instead, show improvements in knowledge. The profile of those workers is consistent with the idea that information is costly. Controlling for various factors reduces the difference due to educational and gender by about one third. While the remaining differences could be due to different preferences over leisure, another possible reason might be financial illiteracy.²¹

The important lesson is that the free availability of information is not sufficient to get informed. Obtaining information seems to be costly and might prevent workers who think that information is of little value to become knowledgeable. Stimulating workers by directly providing them with information reduces that cost and has the predictable effect of improving workers' knowledge. In the first waves the HRS asked only about expected benefits at the expected retirement age and does not ask about expected retirement incentives, thus I cannot tell whether the additional knowledge about benefits does indeed translate into additional

²⁰The reason to use truncated values is that variances are highly sensitive to outliers. Without truncation the variance of the error is even larger in the pre-Statement period. In the HRS, respondents can report weekly, monthly, biyearly, and yearly values. The big discrepancies seem to be due to the few observations with measurement errors in the variable that reports this "frequency" variable.

²¹Another explanation may be that some workers prefer to procrastinate ?.

knowledge about retirement incentives.

In the next section, I test whether and how the new information affects workers' retirement decisions.

4 The Effect of the Statement on Retirement and Social Security Benefit Claiming Behavior

The additional information provided by the Statement can influence workers' behavior in many ways. There may be a "surprise" effect: workers who overestimated their expected Social Security benefits should react by working and saving more, while those who underestimated their benefits should do the opposite. Although changes in labor supply may also happen at the intensive level (hours), I focus on changes at the extensive level (participation). Since forecast errors are approximately symmetrically distributed around zero, these changes may go in both directions. Also, as over time the age at which workers received their first Statement decreases, I should expect these "surprise" effects to weaken. In addition, even if the decision of becoming informed is the sole product of a maximization process with costly information, at the margin the Statement should strengthen the link between Social Security incentives and retirement.

Because of liquidity constraints and the earnings test (earnings above given thresholds reduce current Social Security benefits), the retirement decision is strongly related to the claiming decision. According to the HRS data, half of the time the monthly self-reported retirement date and the monthly self-reported claiming date are not more than 12 months apart from each other. When the difference between the two dates is larger than one year, the difference is mainly due to early retirement. Among those who retire at or after age 62, 75 percent claim and retire within a year.

4.1 Social Security Claiming

Most workers claim at the "Early" and the "Normal" retirement age. Liquidity constraints can explain the spike at age 62 while the other spike is more puzzling, and some economists have suggested that workers may use the NRA as a focal point (?). Another surprising fact

that cannot be easily explained by the incentives is that workers are more likely to claim their benefits within a month of their birthday than just the month before or the month after that period. In particular, they are 20 percent more likely at age 63, 64, and 66 and, less surprisingly, multiple times more likely at age 62 and at the NRA. If the Statement *improves* workers' understanding of the Social Security incentives they should become less likely to claim at these particular ages. I use the SSA's Master Beneficiary Records (1 percent of all retirees) to test whether after receiving a Statement workers become less likely to claim within a month of their date of birth, separately by age.

Figure 2 shows the probability of claiming the Social Security benefits within a month of age 62 (upper-left panel), age 63, 64, or 66 (upper-right panel), Normal Retirement Age (lower-left panel), and age 70 (lower-right panel), both before and after the introduction of the Social Security Statement.²² All the panels show that there is a tendency for people to claim the benefits in January, but there is no discontinuity in the claiming patterns when the Statements are introduced.

It might still be that workers changed their claiming behavior due to the Statements, but that these changes cancel out in the aggregate due to the symmetry around zero of the benefits' forecast errors. The next step is to evaluate the impact that the Statement had on retirement using individual data.

4.2 Retirement

4.2.1 Social Security Incentives

Postponing retirement by one year can generate considerable changes in SSW (the SSW accrual). Positive accruals generate an incentive to work. Figure ?? shows that there are two pronounced retirement rate spikes: at the early retirement age (ERA) and at the Normal Retirement Age (NRA). Around 17 percent of people retire at the age of 62, and among those who do not claim before age 65, 20 percent retire at age 65. Some factors can partially explain this

²²In response to an earlier "crisis" in Social Security financing two decades ago, the US Congress implemented both a reduction in the Normal Retirement Age (NRA) of two months per year for cohorts born in 1938 and afterward, and, starting in 1986, an increase in the delayed retirement credit (?).

clustering: large disutility from work and/or a large discount rate (ERA spike) and discontinuities in the actuarial adjustment rates (NRA spike) (??). ? attribute part of the 62-spike to liquidity constraints and part of the 65-spike to lock-in effects due to Medicare when workers lack alternative health insurance in retirement.²³

In order to analyze whether the Statement makes workers more responsive to Social Security incentives I first need to compute these incentives. Thus I need to forecast earnings and compute future benefits as a function of the retirement age. Below I briefly review the main provisions of the benefit formula and the assumptions needed to compute the Social Security Wealth.

I compute the Social Security benefits $B_t(a)$ for each retirement age using the same assumptions used by the SSA to provide an estimate in the Statement. The Statement assumes that if the worker doesn't retire he/she is likely to earn the same amount he/she earned last year (or the year before if last year's earnings are zero). In other words, real earnings are assumed to follow a random walk, so that the previous year's earnings are the best predictor for future earnings. This assumption is not very different from ?, who assume that real earnings are expected to grow by one percent. Every year, benefits are then computed as a function of age (from age 55 to 70) and as a function of the retirement age (from the worker's actual age to age 70). The benefit rules are held constant, and it is assumed that promised benefits are going to be paid. Workers who retire before age 62 are assumed to claim at age 62.

I do not model the spouse's retirement decision, and I assume that the spouse claims at the earliest possible age.²⁴ The Statement explains what spouse benefits, and survivors benefits are, but it doesn't provide an estimate of these benefits. I estimate retirement models with and without taking into account these additional benefits and the results are generally very similar. I define a spouse as "independent" when his/her own benefits at age 62 are larger than

²³Their explanation is at odds, however, with the evidence from the 1961 change in the early retirement age from 65 to 62. While the ERA has changed suddenly, the spike in retirement has moved very slowly (over 30 years, ?). Based on this evidence, ? suggest that spikes may not be entirely the product of rational decision making but resemble some herd behavior. Additional support for a behavioral explanation of the spikes is provided by the recent increase in the NRA suggested by the 1983 Greenspan Commission. ? shows that the entire 65-spike at which the workers claim their Social Security benefits moved together with NRA. This contradicts the Medicare explanation as the Medicare eligibility at age 65 remained unchanged. The Social Security Statement contains the advice that, "even if you do not retire at age 65, be sure to contact Social Security three months before your 65th birthday to enroll in Medicare."

²⁴Most of the times it is age 62, which also represents the median claiming age.

50 percent of her spouse's benefits at age 62.

Benefits are a function of the weighted average of the highest 35 years of average wage-indexed earnings, called the AIME. Since workers tend to have lower earnings at the beginning of their career than at the end working an additional year normally increases future benefits even at age 62, which generates an additional incentive to work. However, between age 55 and 61 the increase in Social Security benefits is modest. Its median ranges between 1 percent and 2 percent. Starting at age 62 instead, the increase is substantial, since the approximately 8 percent per year actuarial adjustment kicks in. Looking at benefits only doesn't take into account that working an additional year means that benefits are not collected in that year, and that Social Security taxes are paid on the additional earnings up to the maximum taxable threshold. This is clearly stated in the Statement but the Statement does not provide workers with estimates of this intertemporal trade-off. This is why later in the regression I use the simple increase in the benefits as the most naive form of Social Security incentives.

More forward-looking incentives depend on the number of years that workers, and possibly their spouses, expect to collect benefits. It also depends on their discount rate. The SSW is a function of time t and retirement age a :

$$SSW_t(a) = PDV_t(B(a)) = \sum_{t=s}^T \beta^{t-s} p_t(s) B_t(a) \quad (6)$$

Following the literature I use a real discount rate of 3 percent ($\beta = 1.03$).²⁵ $B_t(a)$'s are expressed in 2003 dollars using the CPI, and the conditional probabilities of survival, $p_t(s)$, are based on the SSA's cohort-specific life tables.²⁶ In a second set of regressions, that are available upon

²⁵There is some evidence that discount rates may actually be larger than 3 percent (?). On the other hand, ? argue that in the absence of borrowing constraints it is more appropriate to use a real interest rate instead, which can be assumed to be very low (they use 1 percent). I follow the mainstream literature and use a 3 percent discount rate, though the reduced form model estimated controlling for age seems to be robust to the use of different discount rates. The reason is that controlling for age the effect of the accrual is mostly identified by the accrual's cross-sectional variation within age, while the use of different discount rates generates mainly large differences across age.

²⁶The life tables are prepared by the Office of the Chief Actuary in the Social Security Administration. Projected death rates and life tables are based on Alternative II forecasts for the 1998 Trustees report (taken from the Berkeley Mortality Database). To compute total Social Security benefits (including spouse's benefits and survivors' benefits) when using the tables I'm implicitly assuming that the couple's individual mortalities are independent.

request because the results are very similar, I correct the probabilities of survival for the ratio between the subjective probability of surviving age 75 and the same probability taken from the life tables.²⁷

Because I lack precise information on dependent children, the benefits include dependent benefits and survivors' benefits, related only to the spouse. In that case $p_t(s)$ is a column vector where the entries are: the probability that only the worker survives, the probability that only his wife survives, and the probability that both survive. $B_t(a)$ is a row vector containing the worker's own benefits, the survivors's benefits, and the sum of the worker's own benefits and the dependent spouse's benefits.

The Social Security accrual is the expected gain in SSW from waiting an additional year before retiring and claiming Social Security benefits,²⁸

$$ACC_t(a) = SSW_t(a + 1) - SSW_t(a), \quad (7)$$

while the peak-value (PV) ? is the difference between the maximum SSW and the current SSW,

$$PV_t(a) = \max_x SSW_t(x) - SSW_t(a). \quad (8)$$

Retirement decisions based on PV's and ACC's differ whenever ACC's are not monotonic relative to the retirement age. I also compute relative incentives, $ACC_t(a)/SSW_t(a)$, and $PV_t(a)/SSW_t(a)$. For this reason the sample is restricted to workers with positive Social Security Wealth. If workers are below age 62 and retire, the Social Security Wealth is equal to the Social Security Wealth they will get at age 62 discounted to their age.

I compute the accrual net of Social Security taxes, $tW_t(a)$, assuming, like in ?, that workers bear the entire payroll tax, t (12.4 percent since 1990). Since I do not observe income I do not attempt to try to simulate income taxes, though in the regressions the different tax treatment of Social Security benefits should in part be absorbed by the coefficient on earnings.²⁹

²⁷The RAND version of the HRS contains this variable, called "rliv75r."

²⁸I assume that workers claim and retire in the same year.

²⁹If a beneficiary files a federal tax return as "an individual," ("a couple") and the combined income is between \$25,000 and \$34,000 (\$32,000 and \$44,000) in 2004, he or she pays taxes on 50 percent of the Social Security benefits. If the combined income is more than \$34,000 (\$44,000), up to 85 percent of the Social Security benefits

There is heterogeneity in accruals (in thousands) over age and within age from postponing retirement. Part of it is due to the eligibility to different types of benefits (i.e., dependent spouse's benefits). Differences in earnings histories, current earnings, and Social Security rules account for the rest. Individuals, especially men, who evaluate the future streams of Social Security benefits taking only their own benefits into consideration (either because they have no dependents, or because their spouses are better off by claiming their own benefits) generally face negative or null increases in SSW from additional work. The summary statistics of all the different incentives used are shown in Table 5.

4.2.2 A Measurement Error Model of Optimal Retirement Behavior

Reduced form models of retirement have been used extensively in the retirement literature. ? estimate a probit reduced form model of retirement that incorporates forward-looking Social Security incentives. Their concept is based on the Option Value model of ?, a model that resembles a dynamic programming model although it introduces some important simplifications. Accruals tend to be decreasing with age *except* between ages 61 and 62. Since workers may be forward-looking and incorporate future accruals in their retirement decisions ? and numerous papers that follow their approach use the peak value as the main measure of Social Security incentives. All of these papers use reduced form PV probits, and assume a constant coefficient on the PV.³⁰

I estimate the following linear probability model,

$$R_i = \alpha_i ACC_i + \beta' \tilde{x}_i + \epsilon_i, \quad (9)$$

where R is equal to one when workers report being retired and zero otherwise, ACC is some sort of Social Security incentive to retire, and \tilde{x} denotes the other regressor, including the earnings (y).³¹ The model estimates hazard rates as workers are excluded from the sample once they retire.

are subject to income tax.

³⁰?, instead, use a more structural approach and assume that workers respond differently to incentives depending on their health, age, and year of birth.

³¹Results based on probit regressions are very similar.

First, I assume that α_i is constant across people and independent of the Statement $T \in \{0, 1\}$, while later I allow α_i to vary between the pre and the post-Statement period:

$$\alpha_i = \alpha_0 + \alpha_1 T_i. \quad (10)$$

α_0 is the effect of the accrual for workers in the pre-Statement period.

Substituting α_i into Eq. (9) I get,

$$R_i = [\alpha_0 + \alpha_1 T_i] ACC_i + \beta' \tilde{x}_i + \epsilon_i. \quad (11)$$

In this setup, α_1 represents the difference between the post- and the pre-Statement period in the marginal effect of a unit (\$1,000) increase in the accrual on the probability of retirement:

$$\alpha_1 = \frac{\partial P(R = 1)}{\partial ACC} \Big|_{T_i=1} - \frac{\partial P(R = 1)}{\partial ACC} \Big|_{T_i=0}. \quad (12)$$

In order to control for changes in retirement behavior that may be due to the earnings test (ET), I include the average ET tax.³² The average average tax is 6 percent, but less than 10 percent of workers would be subject to it. The average average tax among workers with a positive tax is 75 percent. The taxed benefits are after being actuarially adjusted added to the worker's future benefits once he stops working. A higher average tax would thus influence worker's retirement in one direction only if he does not take into account the increased future benefits. Table 8 in the Appendix shows the summary statistics for the sample used in the regressions.

All regressions control for the SSW, the SSW of the spouse when she is independent, an independent spouse dummy, the labor force status of the spouse, age dummies, year, year squared, a post-Statement dummy, the level of education, marital status, the own and the spouse's real AIME at age 55, subjective health status dummies, the difference in age relative

³²The average ET tax, based on potential earnings, is $t_{ET} = \min(benefits, (potential\ earnings - ET\ threshold) \times ET\ tax) / benefits$. When potential earnings fall below the ET threshold, the marginal tax and the average tax are zero. Special rules apply the first year a worker claims his benefits. Under these rules, a worker can use a monthly test amount. If she claims and retires during the year, she can get a full Social Security check for any whole month he/she is retired, regardless of his yearly earnings. Since I do not have information on monthly earnings I cannot control for this case, which is why the average tax may be measured with some error.

to the spouse, a no children in the household dummy, veteran status, experience, occupation and industry dummies, and forecasted earnings.

If the researcher observes the true accrual ACC , but workers base their decisions on their perceived and sometimes mismeasured accrual \widehat{ACC} , the estimated effect will be downward biased (relative to workers' actual intentions). The bias will be higher the higher the variance of measurement error $Var(\widehat{ACC} - ACC)$. If the Statement allows workers to get a better estimate not only of their Social Security benefits but also of their retirement incentives *and* this better estimate is used to make better retirement decision, the variance would decrease, reducing this "classical-type" measurement error bias. The coefficients in the post-Statement period would thus in absolute value be larger than in the pre-Statement period.

4.2.3 Results

Let me first discuss the sample that I use for the regressions. The Statement has been sent out in phases, depending on the age, the fiscal year, and the date of birth of workers. This means that workers born in the same year might have started receiving a Statement in different years. I exploit these discontinuities in the phasing in together with the variation in the date of interview of the HRS respondents to select a sample of age in years/year of birth combinations where *at least some, but not all* individuals in an age in years/year of birth group receive a Statement. Table 6 shows the age/year of birth combinations for the HRS linked to the SSA records. The combinations that have at least some but not all workers receiving a Statement are shown in bold. Of this sample 56 percent of individuals receive a Statement. Table 8 shows that controlling for age dummies, year, and year squared almost all other regressors do not on average differ between the pre and the post-Statement period.³³ This shows that the treatment and control group have on average similar characteristics.

In Table 7 each column represents an empirical specification with a different Social Security incentive. The first column shows the results for the ratio between the earliest benefits the worker would receive retiring in the following year and the earliest benefits the worker would receive retiring immediately. In order to estimate this kind of incentives workers do not have to

³³Around 5 percent of the coefficients should turn out to be significant even if the true effect was zero.

compute present discounted values. Most of the information needed to compute this incentive is available in the Statement. As in Eq. 11, I allow k to be different between the pre and the post-Statement period. In the pre-Statement period increasing the benefits by 1 percentage point decreases the self-reported retirement hazard by 0.52 percentage points. The difference between the Post and Pre period coefficient is -11 percentage points (-20 percent compared to the pre Statement effect), with a standard error of 23 percent. Column 2 shows that using the percentage accrual gives, surprisingly, similar results. Measuring accruals in levels tells us that a \$1,000 increase in the accrual decreases the hazard rate of retiring by 0.49 percentage points, while a similar increase in the peak value decreases the hazard rate of retiring by 0.08 percentage points.³⁴ The coefficients on the interaction term keep on being very close to zero, meaning that workers respond to Social Security incentives in a similar way over the entire period. In column 4 shows that after-tax accruals do not change these results. Most treatment effects are very close to zero, but with relatively large standard errors. The coefficients on the SSW are positive but not significant. The coefficients on the SSW show an increase in the post-Statement period, but again not significantly different from zero.

All the alternative specifications tried give similar results: controlling for time only linearly; computing Social Security incentives with a 7 percent discount rate instead of a 3 percent one; computing Social Security incentives assuming that workers do not take dependent spouse's benefits into account; computing Social Security incentives based only on the benefits received at age 62, at the NRA, and at age 70, which are the benefit levels shown in the Statement; correcting Social Security incentives for the worker's subjective probability of survival. I also tried to interact "contacting SSA" with the Statement dummy, despite its endogeneity and there is no evidence of larger responsiveness to the incentives upon receipt of a Statement for those who didn't contact SSA. To avoid the endogeneity issue I tried to condition the sample to workers who are *predicted* to be less likely to have contacted the SSA, but again there was no evidence of significant treatment effects.

In sum, despite having the right sign, none of the "treatment" effects is significantly different

³⁴? estimate a similar regression, though they use a probit and the PV and find a marginal effect of 0.7 percent for the accrual.

from zero, and I cannot rule out that the Statement did not alter workers' retirement behavior. It is certainly unlikely that it made workers a lot more responsive to Social Security incentives.

Let me stress that these results do not mean that information plays no role for workers' retirement behavior. They simply cast some doubts on the possibility that by just giving additional information, even when this information gets absorbed, workers will change their behavior. Notice that these results are not in contrast with ?'s ones that workers respond to their own expectations. One could simply add that ?'s result would probably be stronger when workers have to incur some cost to generate these expectations. Finally, workers might disregard the new information because those that did not get informed before are unable to use the additional information to derive forward-looking incentives.

5 Conclusions

There is empirical evidence that a worker's retirement decision responds to forward-looking retirement incentives. These incentives depend on current and future earnings, and on retirement benefits. Social Security benefits, which represent the most important source of retirement income, are a complicated function lifetime earnings. It is generally assumed that workers know their benefits and are able to compute their retirement incentives.

In order to understand whether this is a reasonable assumption I analyze workers' knowledge. Contacting the SSA represents the single most important channel through which workers learn about their future benefits. I model the probability of contacting the SSA and find evidence that is consistent with the existence of considerable costs of collecting (and processing) information about Social Security benefits: Workers who, for various reasons (health, liquidity, etc.), face simple retirement decisions are less likely to contact the SSA. Additional evidence confirming this result comes from the 1995 introduction of the Social Security Statements. These Statements, which contain an estimate of the worker's benefits if he/she retires at age 62, 65, and 70, generate an exogenous variation in the cost of obtaining information. Upon receiving a Statement workers are more likely to be able to provide a benefit estimate and their benefit estimate tends to be more precise. Controlling for the endogeneity of the decision to

contact the SSA, I find that the whole improvement is concentrated among those workers who don't contact the SSA.

Then I turn to study how this additional information affects workers' retirement behavior. The introduction of the Statement doesn't improve the overall responsiveness to the retirement incentives. While this might at first seem disappointing given the 36 cents per Statement spent by the SSA, it might either mean that workers are already behaving optimally, with the marginal workers having only very small additional benefits from getting informed, or that the information contained in Statement is not sufficient to improve workers' retirement behavior.³⁵ This calls for additional research. Moreover, the Statement might still improve the workers' ability to smooth their consumption upon retirement if workers become less likely to be positively or negatively surprised by the amount of the benefits, given that these surprises act like unexpected changes in permanent income. This possibility also needs to be researched. One way to improve the information required to make better retirement decisions is to provide forecasted benefits at all 9 possible claiming ages, instead of just at 62, at the NRA, and at 70. Moreover, the Statement provides workers with information about their benefits, but it does not calculate a worker's SSW. If this weakens the beneficial effect of the Statement, a possible addition to the Statement could be a table that helps workers calculate their SSW. Since the SSA cannot possibly use individual-specific mortality rates, one easy way to circumvent this problem would be to construct a two-way table that contains "suggested" retirement ages as a function of a worker's expected own and spouse's life-expectancy.

³⁵The Social Security Statement experiment is certainly not as straightforward as providing consumers with tax-inclusive prices to detect their salience (?).

60	0.39	15.04*** (3.05)	-1.84 (3.81)	57.11*** (4.04)	-12.35** (5.01)
61	0.55	9.94*** (2.29)	7.89** (3.29)	57.50*** (4.53)	-19.20*** (5.14)
62	0.59	12.15*** (3.17)	3.19 (4.21)	57.14*** (5.93)	-21.07*** (6.97)
63	0.66	11.59*** (3.87)	3.21 (4.81)	52.63*** (8.12)	-17.09* (8.84)
64	0.67	14.29 (9.38)	-1.73 (9.51)	33.33** (15.76)	1.50 (16.39)

Notes: The regression controls for gender, education, experience, and veteran status. The first column reports the fraction contacting the SSA. “Pre” columns report the fraction of workers who do not provide an estimate during the Pre-Statement period. Pre-Post columns report changes in the probability of providing a benefit estimate. Fractions are computed separately for workers who contacted (first two columns) and those who didn’t contact the SSA (last two columns). Clustered (by individual) standard errors in parentheses. Bootstrapping (using 200 rep.) the standard errors by individual to account for both clustering, and for the variation due to the first-step estimation of the probabilities of misclassification of contacting the SSA has negligible effects on the significance level (results available upon request). * significant at 5 percent; ** significant at 1 percent. *Sample:* HRS 1992-2000, age 55-64.

Table 4: Variance ratio test

	Did not contact SSA			Contacted SSA		
	Standard Dev.		p-value	Standard Dev.		p-value
	Pre-SSS	Post-SSS		Pre-SSS	Post-SSS	
	Forecast error truncated at:					
$ e < \1000	477.24	330.26	0.000	626.15	759.22	1.000
	[625]	[265]		[779]	[254]	
$ e < \500	226.93	204.17	0.032	182.42	171.40	0.125
	[518]	[232]		[701]	[240]	
$ e < \300	154.04	136.24	0.026	129.02	123.14	0.211
	[398]	[196]		[610]	[213]	

Notes: Standard deviation of the errors and p-value of a variance ratio test with null-hypothesis $H_0 : V_{pre}/V_{post} < 1$. Estimates control for the improvement in the standard deviation of the forecast error that is independent of the Statement by using the dashed line version of Figure 1 for the pre-Statement period. Since variances are highly sensitive to outliers I test the null using three truncated versions of the forecast error. Numbers of observations in square brackets. *Sample:* HRS 1992-1996, age 55-65.

Table 5: Summary statistics of Social Security Incentives

Variable	Mean	Std. Dev.	N
Yearly percentage increase in benefits (in %)	4.004	3.537	31563
Percentage accrual, 3%, single	0.05	2.592	31563

Notes: All Social Security incentives are expressed in real 2003 dollars. All regressions additionally control for real AIME, spouse's real AIME, age dummies, year, year squared, industry and occupation dummies, and self-reported health dummies. Clustered (by individual) standard errors in parentheses; * significant at 5 percent; ** significant at 1 percent. *Sample:* HRS linked to administrative data highlighted in Table 6.

A Data

I use the Health and Retirement Survey (HRS) to evaluate how the Statement affects workers' knowledge about their future benefits, and to evaluate what determines whether workers are informed even before receiving the Statement. The data are then matched to administrative records from the SSA to evaluate the effect of the Statement on retirement decisions.

The HRS is a longitudinal, biennial, nationally representative survey of older Americans. I use waves 1 to 6 (1992–2000), and restrict the analysis to workers older than age 55 and younger than age 70 who are not receiving Social Security disability benefits. I also restrict the sample to workers who are in the labor force in 1992, and drop workers from the sample if they die. I restrict the analysis to workers born between 1922 and 1941.³⁶ Workers are matched with their spouses' information. Some workers have expected benefits that are smaller than half of the benefits of their spouse. These workers are excluded from the analysis since they are better off by claiming for their spouses' benefits, and are unlikely to respond to changes in their own SSW. Table 8 in the Appendix shows the summary statistics for the HRS sample used in the regressions.

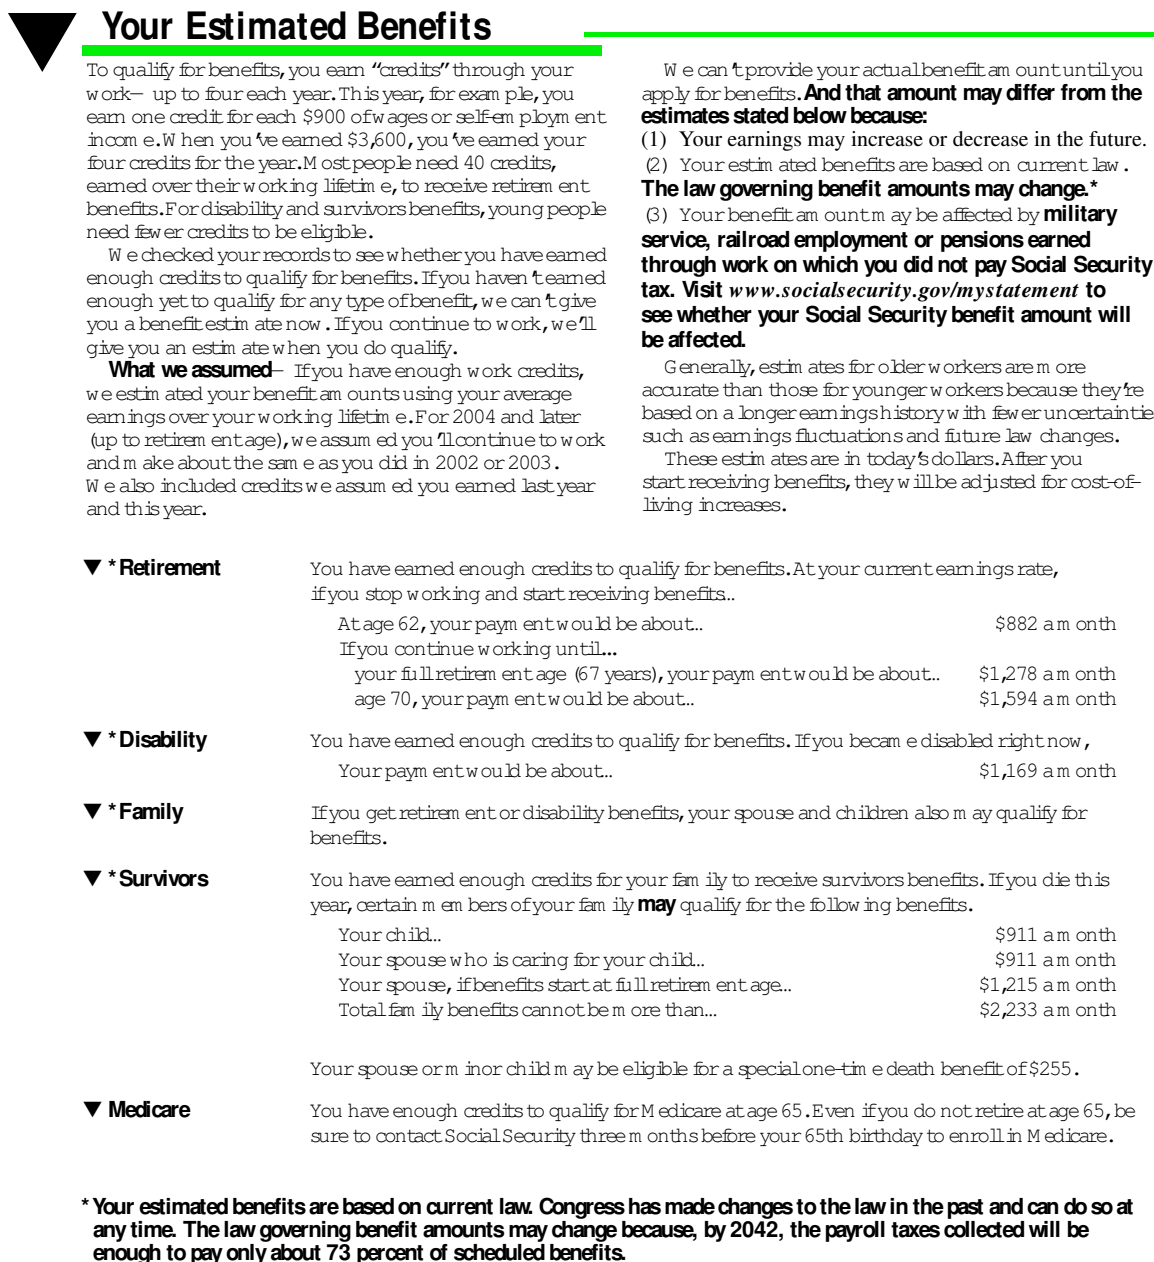

³⁶Some further deletions are made mostly for reasons of miscellaneous data inconsistencies.

Notes: Each line refers to a different regression. The “row” variable is first regressed on just a Statement dummy. The first column shows the estimated constant term, the second the estimate of the post-pre difference. In the third column I additionally control for year, year squared, and for age dummies. Clustered (by individual) standard errors in parentheses; * significant at 5 percent; ** significant at 1 percent. *Sample:* 5,986 observation selected in Table 6.

Figure 3: The Social Security Statement

We based your benefit estimates on these facts:	
Your name...	Wanda Worker
Your date of birth...	May 5, 1963
Your estimated taxable earnings per year after 2003 ...	\$35,051
Your Social Security number (only the last four digits are shown to help prevent identity theft)...	XXX-XX-2004

Help Us Keep Your Earnings Record Accurate

You, your employer and Social Security share responsibility for the accuracy of your earnings record. Since you began working, we recorded your reported earnings under your name and Social Security number. We have updated your record each time your employer (or you, if you're self-employed) reported your earnings.

Remember, it's your earnings, not the amount of taxes you paid or the number of credits you've earned, that determine your benefit amount. When we figure that amount, we base it on your average earnings over your lifetime. If our records are wrong, you may not receive all the benefits to which you're entitled.

▼ **Review this chart carefully** using your own records to make sure our information is correct and that we've recorded each year you worked. You are the only person who can look at the earnings chart and know whether it is complete and correct.

Some or all of your earnings from **last year** may not be shown on your *Statement*. It could be that we still

were processing last year's earnings reports when your *Statement* was prepared. Your complete earnings for last year will be shown on next year's *Statement*. **Note:** If you worked for more than one employer during any year, or if you had both earnings and self-employment income, we combined your earnings for the year.

▼ **There's a limit on the amount of earnings on which you pay Social Security taxes each year.** The limit increases yearly. Earnings above the limit will not appear on your earnings chart as Social Security earnings. (For Medicare taxes, the maximum earnings amount began rising in 1991. Since 1994, all of your earnings are taxed for Medicare.)

▼ **Call us right away at 1-800-772-1213** (7 a.m. - 7 p.m. your local time) if any earnings for years **before last year** are shown incorrectly. If possible, have your W-2 or tax return for those years available. (If you live outside the U.S., follow the directions at the bottom of page 4.)

Your Earnings Record at a Glance

Years You Worked	Your Taxed Social Security Earnings	Your Taxed Medicare Earnings
1979	474	474
1980	1,123	1,123
1981	1,983	1,983
1982	3,293	3,293
1983	4,461	4,461
1984	5,600	5,600
1985	6,950	6,950
1986	8,813	8,813
1987	10,941	10,941

2002	35,051	35,051
2003	Not yet recorded	

Did you know... Social Security is more than just a retirement program? It's here to help you when you need it most.

You and your family may be eligible for valuable benefits:

- ▼ When you die, your family may be eligible to receive survivors benefits.
- ▼ Social Security may help you if you become disabled— even at a young age.
- ▼ It is possible for a young person who has worked and paid Social Security taxes in as few as two years to become eligible for disability benefits.

Social Security credits you earn month with you from job to job throughout your career.

Total Social Security and Medicare taxes paid over your working career through the last year reported on the chart above:

Estimated taxes paid for Social Security:		Estimated taxes paid for Medicare:	
You paid:	\$24,723	You paid:	\$5,820
Your employer paid:	\$24,723	Your employer paid:	\$5,820

Note: You currently pay 6.2 percent of your salary, up to \$87,900, in Social Security taxes and 1.45 percent in Medicare taxes on your entire salary. Your employer also pays 6.2 percent in Social Security taxes and 1.45 percent in Medicare taxes for you. If you are self-employed, you pay the combined employee and employer amount of 12.4 percent in Social Security taxes and 2.9 percent in Medicare taxes on your net earnings.

Some Facts About Social Security

About Social Security and Medicare...

Social Security pays retirement, disability, family and survivors benefits. Medicare, a separate program run by the Centers for Medicare and Medicaid Services, helps pay for inpatient hospital care, nursing care, doctors' fees, and other medical services and supplies to people age 65 and older, or to people who have been receiving Social Security disability benefits for two years or more. Your Social Security covered earnings qualify you for both programs.

Here are some facts about Social Security's benefits:

▼ **Retirement**— If you were born before 1938, your full retirement age is 65. Because of a 1983 change in the law, the full retirement age will increase gradually to 67 for people born in 1960 and later.

Some people retire before their full retirement age. You can retire as early as age 62 and take your benefits at a reduced rate. If you continue working after your full retirement age, you can receive higher benefits because of additional earnings and special credits for delayed retirement.

▼ **Disability**— If you become disabled before full retirement age, you can receive disability benefits after six months if you have:

- enough credits from earnings (depending on your age, you must have earned six to 20 of your credits in the three to 10 years before you became disabled); and
- a physical or mental impairment that is expected to prevent you from doing "substantial" work for a year or more, or result in death.

▼ **Family**— If you're eligible for disability or retirement benefits, your current or divorced spouse, minor children, or adult children disabled before age 22 also may receive benefits. Each may qualify for up to about 50 percent of your benefit amount. The total amount depends on how many family members qualify.

▼ **Survivors**— When you die, certain members of your family may be eligible for benefits:

- your spouse age 60 or older (50 or older if disabled, or any age if caring for your children younger than age 16); and
- your children if unmarried and younger than age 18, still in school and younger than 19 years old, or adult children disabled before age 22.

If you are divorced, your ex-spouse could be eligible for a widow's or widower's benefit on your record when you die.

Receive benefits and still work...

You can continue to work and still get retirement or survivors benefits. If you're younger than your full retirement age, there are limits on how much you can earn without affecting your benefit amount. The limits change each year. When you apply for benefits, we'll tell you what the limits are at that time and whether work would affect your monthly benefits. When you reach full retirement age, the earnings limits no longer apply.

Before you decide to retire...

Think about your benefits for the long term. Everyone's situation is different. For example, be sure to consider the advantages and disadvantages of early retirement. If you choose to receive benefits before you reach full retirement age, your benefits will be permanently reduced. However, you'll receive benefits for a longer period of time.

To help you decide when is the best time for you to retire, we offer a free booklet, *Social Security—Retirement Benefits* (Publication No. 05-10035), that

provides specific information about retirement. You can calculate future retirement benefits on our website at www.socialsecurity.gov by using the *Social Security Benefit Calculators*. There are other free publications that you may find helpful, including:

▼ *Understanding The Benefits* (No. 05-10024)— a general explanation of all Social Security benefits;

▼ *How Your Retirement Benefit Is Figured* (No. 05-10070)— an explanation of how you can calculate your benefit;

▼ *The Windfall Elimination Provision* (No. 05-10045)— how it affects your retirement or disability benefits;

▼ *Government Pension Offset* (No. 05-10007)— explanation of a law that affects spouse's or widow(er)'s benefits; and

▼ *When Someone Misuses Your Number* (No. 05-10064)— what to do if you're a victim of identity theft.

We also have other leaflets and fact sheets with information about specific topics such as military service, self-employment or foreign employment. You can request Social Security publications at www.socialsecurity.gov or by calling us at **1-800-772-1213**.

If you need more information—Visit www.socialsecurity.gov/mystatement on the Internet, contact any Social Security office, call **1-800-772-1213** or write to Social Security Administration, Office of Earnings Operations, P.O. Box 33026, Baltimore, MD 21290-3026. If you're deaf or hard of hearing, call TTY 1-800-325-0778. If you have questions about your personal information, you must provide your complete Social Security number. If your address is incorrect on this *Statement*, ask the Internal Revenue Service to send you a Form 8822. We don't keep your address if you're not receiving Social Security benefits.

Para solicitar una Declaración en español, llame al 1-800-772-1213.
